

ABSTRACT

An automated provisioning and management system for network devices includes a library of commands that are generic to all devices of interest, and device-specific plug-ins for implementing those commands in each of the different devices. A user can select any one of the standard commands and have it applied to a particular device of interest in a manner which is capable of being handled by that device. An interface between the library and a source of configuration information, such as a database, enables the various tasks associated with the provisioning and management of network devices to be automatically carried out on multiple devices, thereby minimizing, or even eliminating, the need to manually configure each such device. Various tools are provided to facilitate the ability of support personnel to identify and monitor functions performed by various devices, as well as detect and correct errors in the operation of those devices.
